| 1 | <p><b>Answer: A</b></p> <p>X consists of two substances R and Y. Therefore it is a mixture. Since Y cools at a fixed temperature, it is a pure substance.</p>                                                                                                                                                                                                                                                                                                                                                                                             |
| 2 | <p><b>Answer: B</b></p> <p>Bromine and molecules in the air are in constant random motion.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3 | <p><b>Answer: D</b></p> <p>When <b>silver nitrate</b> is added to <b>barium iodide</b>, a yellow precipitate of silver iodide is formed. The filtrate is aqueous barium <b>nitrate</b>.</p> <p>When dilute sulfuric acid is added to the filtrate, a <b>white precipitate of barium sulfate</b> is formed. The filtrate contains nitric acid, which is made up of hydrogen ions and nitrate ions.</p>                                                                                                                                                     |
| 4 | <p><b>Answer: C</b></p> <p>Helium, having a proton number of 2, has an electronic configuration of 2, and has 2 electrons in the outer shell.</p> <p>Lithium, having a proton number of 3, has an electronic configuration of 2,1, has 1 electron in the outer shell.</p> <p>Neon, having a proton number of 10, has an electronic configuration of 2,8, has 8 electrons in the outer shell.</p>                                                                                                                                                          |
| 5 | <p><b>Answer: C</b></p> <p>since X forms cation of <math>X^{2+}</math>, the ionic compound formed with fluorine is <math>XF_2</math>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6 | <p><b>Answer: A</b></p> <p>Ammonium chloride consists of ammonium <b>ion</b> and chloride <b>ion</b> – an <b>ionic bond</b> exists between them.</p> <p>Ammonium ion has <b>covalent bonds</b> between nitrogen and hydrogen <b>atom</b></p>                                                                                                                                                                                                                                                                                                              |
| 7 | <p><b>Answer: A</b></p> <p>The <b>intermolecular forces of attraction</b> between covalent molecules are <b>overcome</b> when the covalent liquid boils.</p>                                                                                                                                                                                                                                                                                                                                                                                              |
| 8 | <p><b>Answer: C</b></p> <p>No. of moles of chlorine gas = <math>\frac{71}{71} = 1 \text{ mol}</math></p> <p>Since volume ratio = mole ratio for gases,</p> <p>No. of moles of phosphorus vapour = 1 mol</p> <p><b>Molar mass</b> of phosphorus molecule = <math>\frac{\text{mass}}{\text{no. of moles}} = \frac{124}{1} = 124 \text{ g/mol}</math></p> <p>No. of moles of phosphorus atoms in a molecule of phosphorus</p> $= \frac{\text{mass}}{\text{atomic mass}} = \frac{124}{31} = 4 \text{ mol}$ <p>Therefore, the formula is <math>P_4</math>.</p> |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 16 | <p><b>Answer: D</b></p> <p>The enthalpy change (<math>\Delta H</math>) of the backward reaction is +23.0 kJ/mol.</p> <p>Hence, the activation energy of the backward reaction is the sum of the activation energy and the enthalpy change of the backward reaction.</p> <p><math>E_a</math> of the <b>backward</b> reaction = 23 + 5.4 = +28.4 kJ/mol</p>                                                                                                                                                                                                                                                                                                                                                             |
| 17 | <p><b>Answer: B</b></p> <p>In an exothermic reaction, the energy given out when bonds are formed is greater than the energy absorbed to break the bonds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 18 | <p><b>Answer: A</b></p> <p>Option A: Energy change when one mole of potassium chloride dissolves in water</p> $= \frac{+720}{\frac{4}{39+35.5}} = +13.4 \text{ kJ/mol}$ <p>Option B: Powdered potassium chloride will dissolve in a faster rate but the energy change will be the same.</p> <p>Option C: Since the energy change is positive, it is an endothermic reaction. The energy level of the products is higher than the reactants.</p> <p>Option D: Since it is an endothermic reaction, the temperature of the reaction mixture after the reaction will be <u>lower</u> than water before the experiment. The temperature change, <math>T_{\text{final}} - T_{\text{initial}}</math>, will be negative.</p> |
| 19 | <p><b>Answer: B</b></p> <p>Statement 1: the reaction time remained constant at 10 s when 0.92 mol/dm<sup>3</sup> to 1 mol/dm<sup>3</sup> of sulfuric acid was used. Hence, when 1.5 mol/dm<sup>3</sup> of sulfuric acid was used, the approximate reaction time is also 10 s.</p> <p>Statement 2: the rate of reaction is inversely proportional to reaction time. Since the <u>reaction time decreases</u> with <u>increasing concentration</u>, the <u>rate of reaction increases</u> with increasing concentration.</p> <p>Statement 3: since sulfuric acid is in excess, and the same mass of magnesium is used in each experiment, the same volume of hydrogen gas would be produced in each experiment.</p>     |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>20</b> | <p><b>Answer: A</b></p> <p>In step 1:</p> <p>Bromine oxidised sulfur in <math>\text{SO}_2</math> from an oxidation state of +4 in <math>\text{SO}_2</math> to +6 in <math>\text{H}_2\text{SO}_4</math>.<br/>Sulfur dioxide reduced bromine in <math>\text{Br}_2</math> from an oxidation state of 0 in <math>\text{Br}_2</math> to -1 in <math>\text{HBr}</math>.<br/>Hence <math>\text{Br}_2</math> is the oxidising agent and <math>\text{SO}_2</math> is the reducing agent.</p> <p>In step 2:</p> <p>Hydrogen bromide reduced chlorine in <math>\text{Cl}_2</math> from an oxidation state of 0 in <math>\text{Cl}_2</math> to an oxidation state of -1 in <math>2\text{HCl}</math>.<br/>Chlorine oxidised bromine in <math>\text{HBr}</math> from an oxidation state of -1 in <math>\text{HBr}</math> to 0 in <math>\text{Br}_2</math>.<br/>Hence <math>\text{Cl}_2</math> is the oxidising agent and <math>\text{HBr}</math> is the reducing agent.</p> |
| <b>21</b> | <p><b>Answer: B</b></p> <p>Hydrogen sulfide acts as an acid and reacts with lead carbonate to form a salt, water, and carbon dioxide gas.<br/>This reaction is not a redox reaction.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>22</b> | <p><b>Answer: A</b></p> <p>Sodium hydroxide, being an alkali, has the highest pH compared to the other solutions which are acids.<br/>Sulfuric acid, being a dibasic acid, has the highest concentration of <math>\text{H}^+</math> ions, so it has the lowest pH.<br/>Ethanoic acid, being a weak acid, has a lower concentration of <math>\text{H}^+</math> ions compared to hydrochloric acid. Hence, it has a higher pH than hydrochloric acid.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>23</b> | <p><b>Answer: C</b></p> <p>Option A: Copper does not react with acid.<br/>Option B: Lead(II) sulfate is an insoluble salt.<br/>Option C: Magnesium chloride can be prepared by reacting magnesium with hydrochloric acid or magnesium carbonate and hydrochloric acid.<br/>Option D: Sodium carbonate is soluble in water.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>24</b> | <p><b>Answer: A</b></p> <p>Gas Q is an <b>element</b> that can be obtained by the cracking of crude oil.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>25</b> | <p><b>Answer: A</b></p> <p>Option A: The reactivity of halogens decreases down the group. It is less able to be reduced down the group. Thus, the ability as an oxidizing agent decreases down the group.<br/>Option B, C, D: The boiling points, colour intensity and density <u>increases</u> down the group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>26</b> | <p><b>Answer: D</b></p> <p>T is magnesium, U is aluminium, V is silicon, W is phosphorus.</p> <p>Melting point - <math>V &gt; W</math>: Silicon, having a giant molecular structure, has a higher melting point than W, which has a simple molecular structure.</p> <p>Electrical conductivity – <math>T &gt; W</math>: Magnesium, having a giant metallic structure, is able to conduct electricity unlike W, phosphorus, which has a simple molecular structure.</p> <p>Forms basic oxides – T: Magnesium reacts with oxygen to form magnesium oxide, which is basic as it reacts with acids.</p> |
| <b>27</b> | <p><b>Answer: B</b></p> <p>Iron is magnetic – it can be obtained through Step 1</p> <p>Aluminium is lighter than chromium and copper. Transition metals such as chromium and copper has high density. Thus aluminium can be obtained through Step 2.</p>                                                                                                                                                                                                                                                                                                                                            |
| <b>28</b> | <p><b>Answer: B</b></p> <p>Option 1: electrolysis of molten metal oxide enables metal X to be obtained at the cathode.</p> <p>Option 2: metal X is below carbon in the reactivity series; it can be obtained by reduction of metal oxide with carbon.</p> <p>Option 3: metal X is more reactive than copper. Copper is unable to displace metal X from the oxide of metal X.</p>                                                                                                                                                                                                                    |
| <b>29</b> | <p><b>Answer: A</b></p> <p>Copper, being a less reactive metal than magnesium, forms a carbonate that is less thermally stable than magnesium carbonate. Thus, the time taken for a white precipitate to form in limewater is shorter for copper(II) carbonate than for magnesium carbonate.</p> <p>Potassium carbonate is a thermally stable metal carbonate which does not decompose on heating.</p>                                                                                                                                                                                              |
| <b>30</b> | <p><b>Answer: D</b></p> <p>Option A, B and C: redox reactions</p> <p>Option D: this is an acid-base reaction – silicon dioxide is an acidic oxide and calcium oxide is a basic oxide.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>31</b> | <p><b>Answer: C</b></p> <p>Option A: The increase in population of cattle would lead to an <u>increase</u> in the amount of carbon dioxide because of respiration.</p> <p>Option B: The use of electric cars <u>reduces</u> the emission of carbon dioxide.</p> <p>Option C: When there are more trees, they can take in more carbon dioxide and this <u>reduces</u> the amount of carbon dioxide in the air. It does not produce any methane so the amount of methane remains negligible.</p> <p>Option D: With a decrease in ocean size, there is less ocean uptake which would lead to less carbon dioxide being trapped, leading to an <u>increase</u> in amount of carbon dioxide in the air.</p> |
| <b>32</b> | <p><b>Answer: C</b></p> <p>Nitrogen dioxide and sulfur dioxide are acidic gases which, when dissolved in water, forms acid rain.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>33</b> | <p><b>Answer: B</b></p> <p>Option A: it has double bonds between <u>carbon</u> atoms (due to its unsaturation).</p> <p>Option B: it reacts with hydrogen to form margarine, which exists as a solid at room temperature.</p> <p>Option C: it reacts with <u>hydrogen</u> to form margarine.</p> <p>Option D: it turns aqueous bromine from brown to colourless.</p>                                                                                                                                                                                                                                                                                                                                    |
| <b>34</b> | <p><b>Answer: C</b></p> <p>Option A: Fraction I contains a mixture of hydrocarbons with a small number of carbon atoms, not just methane.</p> <p>Option B: Fraction II is used as fuel</p> <p>Option C: The fraction that is the highest in the fractionating column has the <u>lowest</u> boiling point.</p> <p>Option D: Fraction I is most flammable.</p>                                                                                                                                                                                                                                                                                                                                           |
