PAPER 2 (SECTION A)

Question		Answer	Mark
A1	a	M	1
	b	R	1
	c	MQ ₃	1
	d	T	1
	e	Q and Z	1
	f	RQ ₄	1
A2	a	The perfume molecules/particles are always in random motion and will diffuse from a region of higher concentration to a region of lower concentration.	1
	b	The particles must be packed closely together and in disorderly arrangement. The label "a few seconds later" should be changed to a few minutes/hours later.	1 1
	c	The distance moved by the ions in beaker B will be larger than that in beaker A. Since the water in beaker B is at a higher temperature of 30 °C, the ions will gain more heat from it and hence possess higher kinetic energy resulting in higher rate of diffusion.	1 1

		The distance moved by V^{2+} ions in beaker C will be larger than Cu^{2+} ions in beaker A. V has an A_r of 51 while Cu has an A_r of 64. V^{2+} ions will diffuse faster due to their lower mass and cover a larger distance in the same amount of time.	1 1																					
A3	a	carboxylic acid alkene alcohol	1																					
	bi	Add aqueous bromine changes reddish-brown bromine to colourless	1 1																					
	bii	B is a weak acid which dissociate partially when dissolved in water to produce a low concentration of H^+ ions.	1																					
	biii	D will be oxidised to form ethanoic acid.	1 1

mole ratio		$3.33 \div 3.33 = 1$	$6.7 \div 3.33 = 2$	$3.33 \div 3.33 = 1$																				
empirical formula	CH_2O																							
cii	Compound B Compound B has molecular formula $C_2H_4O_2$ /the ratio of C:H:O is 1:2:1.	1																						
A4	a	<table><tr><td>halogen</td><td>colour and state at room temperature and pressure</td></tr><tr><td>chlorine</td><td>yellow green colour and gaseous state</td></tr><tr><td>bromine</td><td>reddish brown colour and liquid state</td></tr><tr><td>iodine</td><td>purple black colour and solid state</td></tr></table>	halogen	colour and state at room temperature and pressure	chlorine	yellow green colour and gaseous state	bromine	reddish brown colour and liquid state	iodine	purple black colour and solid state	colour [1] state [1]													
		halogen	colour and state at room temperature and pressure																					
		chlorine	yellow green colour and gaseous state																					
		bromine	reddish brown colour and liquid state																					
	iodine	purple black colour and solid state																						
bi	The reactivity of the halogens decreases down the Group. (must state but no mark) Chlorine, being placed on top of bromine and iodine, is the most reactive as it can displace both bromine and iodine from their respective halide solutions. Bromine, being placed below chlorine but above iodine, is less reactive than chlorine and hence unable to displace chlorine from the chloride solution, but more reactive than iodine and hence can displace iodine from the iodide	1 1																						

		solution. Iodine, being placed below chlorine and bromine, is the most unreactive as it neither displace chlorine nor bromine from their respective halide solutions.	
	bii	In A, aqueous bromine has displace iodine from aqueous iodide forming the brown aqueous iodine. In B, aqueous iodine is present and did not undergo any reaction.	1
	c	The fluorine molecule gains two electrons readily during chemical reactions and is reduced to two fluoride ions.	1
	di	Although the <i>Cl</i> atom reacted with the O_3 molecule to form <i>ClO</i> , the <i>ClO</i> reacts with another ozone molecule to form back <i>Cl</i> atom. Hence, the <i>Cl</i> atom remains chemically unchanged at the end of the reaction.	1
	dii	<i>Cl</i> atoms will react and break down O_3 molecules repeatedly in the presence of UV light, causing ozone depletion. This will allow more harmful UV radiation from the sun to enter the atmosphere and cause skin cancer or eye damage.	1 1
A5	a	$2H_2 + O_2 \rightarrow 2H_2O$	1
	b	Since $2H_2 \equiv O_2$, volume of O_2 needed = $500 \div 2 = 250 \text{ cm}^3$ volume of air needed =	1 1
	c	Aqueous potassium hydroxide contains free mobile ions but not water which consists of neutral covalent molecules.	1
	d		product [1] $E_a(1)$ [1] $E_a(2)$ [1] ΔH [1]
A6	a	Heat the solution in a beaker. This will remove the water in the solution thereby causing the solution to become concentrated.	1 1
	bi	$(NH_4)_2SO_4 + O_2 \rightarrow N_2 + 4H_2O + SO_2$	formula [1] balancing [1]
	bii	nitrogen: -3 to 0 sulfur: +6 to +4	1 1
	c	manufacture of detergents/fertilisers	1

	d	Because large amount of energy is required for heating in process 2, the processes do not follow the principle of using minimum amounts of energy.	1
		Both processes 1 and 2 use ammonium sulfate waste. Process 2 uses oxygen from air which is renewable. Hence both processes follow the principle of using raw materials which are renewable or use waste from other processes.	1
		Process 1 produces only water while process 2 produces water and nitrogen, which are all harmless.	1

PAPER 2 (SECTION B)

Question		Answer	Mark
B7	a	Both LDPE and LLDPE contain <u>side chains</u> that are made up of <u>only carbon and hydrogen atoms</u> . However, <u>LDPE</u> contains <u>side chains that have more than one carbon atom</u> while <u>LLDPE</u> contains <u>side chains</u> with only <u>one carbon atom</u> .	1 1
	b	Empirical formula for LDPE is CH ₂ . For LDPE with 4000 carbon atoms: Total molecular mass = 4000 x 14 = 56 000 Total mass of 1 mol of LDPE = 56 000 x 1 = 56 000 g Total mass of 1 molecule of LDPE = 56 000 ÷ (6 x 10 ²³) = 9.33 x 10 ⁻²⁰ g For LDPE with 40 000 carbon atoms: Total molecular mass = 40 000 x 14 = 560 000 Total mass of 1 mol of LDPE = 560 000 x 1 = 560 000 g Total mass of 1 molecule of LDPE = 560 000 ÷ (6 x 10 ²³) = 9.33 x 10 ⁻¹⁹ g Range between 9.33 x 10 ⁻²⁰ and 9.33 x 10 ⁻¹⁹ g	1 1 1
	ci	LDPE and LLDPE have side chains to push the polymer chains away from each other while <u>HDPE</u> has no side chains. Hence, <u>HDPE polymer chains</u> can be <u>arranged closer together</u> with more molecules per unit volume, making it <u>more dense</u> .	1 1
	cii	LDPE has more side chains than LLDPE and HDPE, hence LDPE has a <u>lower softening temperature</u> and is <u>weaker</u> than the other two polymers. Thus, it is <u>less suitable</u> to be used as <u>building materials, packaging or hot drinks containers</u> .	1 4 ¹
2022 Answer			

	di	$ \begin{array}{ccccccc} & & & \text{CH}_3 & & & \\ & & & & & & \\ \text{H} & \text{H} & \text{H} & \text{CH}_2 & \text{H} & \text{H} & \\ & & & & & & \\ -\text{C} & -\text{C} & -\text{C} & -\text{C} & -\text{C} & -\text{C}- & \\ & & & & & & \\ \text{H} & \text{H} & \text{H} & \text{H} & \text{H} & \text{H} & \end{array} $	1
	dii	$ \begin{array}{ccc} & \text{CH}_3 & \\ & & \\ \text{H} & \text{CH}_2 & \\ & & \\ \text{C} = \text{C} & & \\ & & \\ \text{H} & \text{H} & \end{array} \qquad \begin{array}{ccc} & \text{CH}_3 & \\ & & \\ & \text{CH}_2 & \\ & & \\ & \text{CH}_2 & \\ & & \\ \text{H} & \text{CH}_2 & \\ & & \\ \text{C} = \text{C} & & \\ & & \\ \text{H} & \text{H} & \end{array} $	2
B8	a	Lithium and beryllium tend to <u>lose electrons to form positive ions</u> and <u>ionic compounds</u> , hence the elements show metallic properties.	1
		From boron to fluorine, the elements tend to <u>share electrons</u> with other <u>non-metal</u> elements to form <u>molecules</u> and <u>covalent compounds</u> , hence the elements show non-metallic properties.	1
		Neon <u>does not react</u> with other elements to form compounds as it is stable and has a <u>completely filled valence shell of electrons</u> .	1
	b	Lithium has a <u>giant metallic structure</u> with <u>metallic bonds between valence electrons and positive ions</u> . A moderate amount of energy is needed to overcome the metallic bonds.	1
		Graphite has a <u>giant molecular structure</u> with <u>strong covalent bonds between atoms</u> . A large amount of energy is needed to overcome the strong covalent bonds.	1
		Oxygen has a <u>simple molecular structure</u> with <u>weak intermolecular forces of attraction</u> . Little energy is needed to overcome the intermolecular forces of attraction.	1
		As <u>more energy</u> is needed to <u>overcome covalent bonds</u> in graphite <u>than metallic bonds</u> in lithium, which in turn requires more energy to overcome compared to <u>intermolecular forces of attraction</u> in oxygen.	

		Hence, <u>graphite</u> has a very <u>high melting point</u> , <u>lithium</u> has a <u>low melting point</u> and <u>oxygen</u> has a <u>very low melting point</u> .	1
		The <u>mobile valence electrons</u> in <u>lithium</u> and <u>graphite</u> allows them to <u>conduct electricity</u> . <u>Oxygen</u> is <u>unable</u> to <u>conduct electricity</u> as it <u>does not contain any mobile charged particles</u> .	1
EIT	a	Anode: $4\text{OH}^- \rightarrow \text{O}_2 + 2\text{H}_2\text{O} + 4\text{e}^-$ Cathode: $2\text{H}^+ + 2\text{e}^- \rightarrow \text{H}_2$	1
HER			1
B9		In both experiments, reactions at both electrodes are the same. In both experiments, <u>hydrogen ions</u> are preferentially discharged over sodium ions as hydrogen ions <u>gain electrons more easily</u> than sodium ions to form <u>hydrogen gas</u> . In experiment 2, <u>hydroxide ions</u> are preferentially discharged over chloride ions as hydroxide ions <u>lose electrons more easily</u> than chloride ions to form <u>oxygen gas</u> . In experiment 1, <u>only</u> hydroxide anions are present and <u>hydroxide ions</u> are <u>discharged</u> to form <u>oxygen gas</u> . Therefore, the ratio of the volume of gases collected is the same in both experiments.	1
		As the <u>same number of moles electrons</u> are involved in the reaction at both electrodes, <u>double the number of moles of hydrogen gas</u> is formed compared to oxygen gas. Hence, <u>double the volume of hydrogen gas</u> is formed compared to oxygen gas.	1
	b	In <u>experiment 3</u> , <u>chlorine gas</u> is produced at the <u>anode</u> instead of <u>oxygen gas</u> . In both experiments, <u>hydrogen gas</u> will be produced at the <u>cathode</u> .	1
	c	Colour in experiment 2: green Colour in experiment 3: violet	1
		In experiment 2, as <u>hydrogen ions</u> and <u>hydroxide ions</u> are both <u>discharged</u> , the <u>pH</u> of the electrolyte <u>remains at 7</u> . In experiment 3, <u>hydrogen ions</u> and chloride ions are <u>discharged</u> , leaving <u>sodium hydroxide</u> in the <u>electrolyte</u> . Hence, the <u>electrolyte</u> becomes <u>more alkaline</u> .	1
OR	a	Experiment 1 Zinc rod: $\text{Zn} \rightarrow \text{Zn}^{2+} + 2\text{e}^-$ Aqueous copper(II) sulfate: $\text{Cu}^{2+} + 2\text{e}^- \rightarrow \text{Cu}$	1
B9		<u>Zinc is more reactive than copper</u> , hence <u>zinc displaces copper</u> from the <u>aqueous copper(II) sulfate</u> solution.	

	The <u>blue solution turns colourless</u> as <u>copper(II) ions</u> in the solution is <u>replaced by zinc ions</u>. A <u>red-brown solid</u> is deposited due to <u>copper metal</u> being formed. Experiment 2 Cathode: $\text{Cu}^{2+} + 2\text{e}^- \rightarrow \text{Cu}$ Anode: $4\text{OH}^- \rightarrow \text{O}_2 + 2\text{H}_2\text{O} + 4\text{e}^-$ <u>Copper(II) ions</u> are preferentially discharged over hydrogen ions as copper(II) ions <u>gain electrons more easily</u> than hydrogen ions to form copper metal. Hence, <u>blue solution turn colourless</u>. <u>Red-brown solid</u> is deposited at the <u>cathode</u> due to <u>copper metal</u> formed. <u>Hydroxide ions</u> are preferentially discharged over sulfate ions as hydroxide ions <u>lose electrons more easily</u> than sulfate ions to form oxygen gas. <u>Effervescence</u> of colourless gas is observed at the <u>anode</u> due to <u>oxygen gas</u> formed.	1
	b Experiment 1: The <u>mass</u> of the solution <u>increases</u> as there is the <u>same number of moles of zinc ions formed</u> and the <u>copper(II) ions reduced</u>. The <u>zinc ions</u> replacing the copper(II) ions have a <u>higher relative atomic mass</u>. Experiment 2: The <u>mass</u> of the solution <u>decreases</u> as <u>copper(II) ions</u> are <u>reduced</u> to form <u>copper</u> that coats on the cathode and <u>hydroxide ions</u> are <u>oxidised</u> and lost as <u>oxygen</u> gas at the anode. The ions discharged are not replaced.	2 1
	c In experiment 3, <u>copper anode dissolves</u> instead of <u>effervescence</u> being observed. <u>Copper anode</u> is <u>oxidised</u> to <u>formed copper(II) ions</u> instead of <u>hydroxide ions</u> being <u>discharged</u>. <u>Blue solution remains</u>. For <u>every one mole of copper(II) ions discharged</u> from the cathode, <u>one mole of copper(II) ions dissolves</u> into the solution from the anode. Hence, the <u>concentration of copper(II) ions</u> remains <u>unchanged</u>.	1 1
