**Interpretation of Spectra**

- 1 The spectra shown below were obtained from compound **Q**, which contains the element carbon, hydrogen, nitrogen and oxygen.

Consider the NMR, mass and IR spectra in turn. Explain what information each spectrum gives about **Q**. Hence give a possible structure for the compound.

### NMR

| $\delta$ /ppm | Multiplicity | No of H | Deduction                                                                                                         |
|---------------|--------------|---------|-------------------------------------------------------------------------------------------------------------------|
| 7-8           | Multiplet    | 5       | <br>Monosubstituted phenyl ring |
| 2.1           | Singlet      | 3       | -CH <sub>3</sub> with no H on adjacent C                                                                          |
| 3.1           | Singlet      | 1       | Since the peak disappear on adding D <sub>2</sub> O, it is a labile proton, attached to an electronegative atom.  |

### MS

M : M+1

16.5 : 1.47

100 : 1.1 n

No. of carbon atoms =  $(100/1.1)(1.47/16.5) = 8$

Given Q contains C, H, O and N,

Peak at m/e 135 could be molecular ion C<sub>8</sub>H<sub>9</sub>NO<sup>+</sup>.

Structure of Q could be A or B.

A

B

| m/e |          | Fragment                                                                            |
|-----|----------|-------------------------------------------------------------------------------------|
| 93  | 135 – 42 |  |
| 43  | -        |  |

Absence of m/e at 105 suggest absence of C<sub>6</sub>H<sub>5</sub>CO<sup>+</sup>.

From the fragment ions, structure of Q is **B**.

### IR

Presence of N-H at 3300 cm<sup>-1</sup>

Presence of amide functional group.

- 2 Interpret the following spectra and use them to suggest a structure for the unknown compound.

### MS

peak at m/e 91 is  $[\text{C}_6\text{H}_5\text{CH}_2]^+$  (benzyl or tropylium cation)

peak at m/e 77 is  $[\text{C}_6\text{H}_5]^+$

peak at m/e 43 is  $[\text{CH}_3\text{CO}]^+$

### UV/VIS

Compound shows several absorptions within UV/VIS region, suggesting presence of a conjugated  $\pi$ -system

### IR

C-H stretch at  $3100\text{cm}^{-1}$

Strong absorption at  $1750\text{cm}^{-1}$  due to C=O stretch.

### NMR

| $\delta$ / ppm | No. of $^1\text{H}$ | Multiplicity | Deductions                                                                                                        |
|----------------|---------------------|--------------|-------------------------------------------------------------------------------------------------------------------|
| 2.1            | 3                   | s            | - <u>CH</u> <sub>3</sub> with no H on adj C<br>Deshielded by electron-withdrawing ketone group                    |
| 3.7            | 2                   | s            | - <u>CH</u> <sub>2</sub> - with no H on adj C<br>Deshielded by ring current and electron-withdrawing ketone group |
| 7.1 – 7.4      | 5                   | m            | Aromatic H on mono-substituted phenyl ring                                                                        |

Structure:

3 Deduce the structure of compound **A**, giving your reasoning.

[8]

**IR**

| absorption | bond |
|------------|------|
| 1740       | C=O  |
| 1200       | C–O  |

- Absence of peak at 3230 to 3500  $\text{cm}^{-1}$  suggests absence of O–H stretch  
 ⇒ No alcohol
- The presence of a C–O (strong and broad) at 1200  $\text{cm}^{-1}$  and C=O at 1740  $\text{cm}^{-1}$  confirm the identity of an ester functional group.

## NMR

| chemical shift /ppm | splitting pattern | No. of adjacent protons | relative peak area | group responsible                                                         |
|---------------------|-------------------|-------------------------|--------------------|---------------------------------------------------------------------------|
| 1.15                | triplet           | 2                       | 3                  | – <u>CH<sub>3</sub></u> ( <b>a</b> ) adj to a –CH <sub>2</sub> –          |
| 1.25                | triplet           | 2                       | 3                  | – <u>CH<sub>3</sub></u> ( <b>b</b> ) adj to a –CH <sub>2</sub> –          |
| 2.30                | quartet           | 3                       | 2                  | – <u>CH<sub>2</sub></u> CO–<br>(adjacent to a –CO– and –CH <sub>3</sub> ) |
| 4.15                | quartet           | 3                       | 2                  | –O <u>CH<sub>2</sub></u> –<br>(adjacent to a –O– and –CH <sub>3</sub> )   |

MS

| m/e | species                                 |  |
|-----|-----------------------------------------|--|
| 102 | $(\text{C}_5\text{H}_{10}\text{O}_2)^+$ |  |
| 57  | $(\text{CH}_3\text{CH}_2\text{CO})^+$   |  |
| 29  | $(\text{CH}_3\text{CH}_2)^+$            |  |

- 4 The  $^1\text{H}$  NMR signals of protons on carbon atoms adjacent to  $\text{C}=\text{C}$  bonds can be split by protons at the far end of the  $\text{C}=\text{C}$  bond.

For example, protons  $\text{H}_\text{A}$  and  $\text{H}_\text{C}$  will split each other with a small coupling constant  $J_{\text{AC}}$ . Protons  $\text{H}_\text{B}$  and  $\text{H}_\text{C}$  will also split each other with coupling constant  $J_{\text{BC}}$ .  $J_{\text{AC}}$  and  $J_{\text{BC}}$  are often not equal.

Protons  $\text{H}_\text{A}$  and  $\text{H}_\text{B}$  may not be equivalent because of the restricted rotation around the  $\text{C}=\text{C}$  bond.

- (a) Propanone undergoes the following sequence of reactions.

The infra-red and  $^1\text{H}$  NMR spectra of compound **C** are shown in Fig. 2.1 and Fig. 2.2.

Fig. 2.1 The infra-red spectrum of compound **C**

Fig. 2.2 The  $^1\text{H}$  NMR spectrum of compound **C**

The mass spectrum of **C** shows major peaks at  $m/z$  values of 15, 43, 58, 101 and a small  $\text{M}^+$  peak at  $m/z$  116.

- (i) Use this information to deduce the structure of **C**.  
Explain your reasoning.

[6]

**IR:**

| Wavenumber of absorbance / $\text{cm}^{-1}$             | Interpretation              |
|---------------------------------------------------------|-----------------------------|
| Strong absorption at $1700\text{ cm}^{-1}$              | C=O stretch in ketone       |
| Strong absorption at $2800\text{--}3000\text{ cm}^{-1}$ | Aliphatic C–H stretch       |
| Broad and strong peak at $3350\text{ cm}^{-1}$          | O–H bond stretch in alcohol |

Presence of alcohol and ketone in **C**

**C** has a  $M_r$  of 116. Based on IR, it has two oxygen atoms (due to ketone and alcohol). Based on NMR, there are 12 hydrogen atoms.

Hence, no of C is  $(116 - 2 \times 16 - 12 \times 1) / 12 = 6$  and molecular formula is  $\text{C}_6\text{H}_{12}\text{O}_2$ .

**MS:**

| m/z | Interpretation                                                                                                                                                                                                                   |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | $[\text{CH}_3]^+$                                                                                                                                                                                                                |
| 43  | $[\text{CH}_3\text{CO}]^+$                                                                                                                                                                                                       |
| 58  | $\left( \begin{array}{c} \text{OH} \\   \\ \text{CH}_3 - \text{C} - \text{CH}_2 \end{array} \right)^+$                                                                                                                           |
| 101 | $116 - 101 = 15$<br>Loss of $\text{CH}_3$ group. Hence m/z = 101 is $\text{C}_5\text{H}_9\text{O}_2$<br>$[\text{CH}_3\text{COCH}_2\text{C}(\text{OH})\text{CH}_3]^+$ or<br>$[\text{COCH}_2\text{C}(\text{OH})(\text{CH}_3)_2]^+$ |
| 116 | $\left( \begin{array}{c} \text{OH} \qquad \text{O} \\   \qquad \parallel \\ \text{CH}_3 - \text{C} - \text{CH}_2 - \text{C} - \text{CH}_3 \\   \\ \text{CH}_3 \end{array} \right)^+$                                             |

**NMR:**

| $\delta$ /ppm | Multiplicity    | No. of adjacent protons | No of H | Deduction                                                           |
|---------------|-----------------|-------------------------|---------|---------------------------------------------------------------------|
| 1.5           | Singlet         | 0                       | 6       | Two $-\text{CH}_3$ adjacent to to C with no H                       |
| 2.5           | Singlet         | 0                       | 3       | $-\text{CH}_3$ adjacent to $\text{C}=\text{O}$ (no H on adjacent C) |
| 2.7           | Singlet         | 0                       | 2       | $-\text{CH}_2$ adjacent to $\text{C}=\text{O}$ (no H on adjacent C) |
| 4.0           | Singlet (broad) | 0                       | 1       | Labile $-\text{O}-\text{H}$                                         |

Structure of **C**:

The infra-red and  $^1\text{H}$  NMR spectra of compound **D** are shown in Fig. 2.3 and Fig. 2.4.

Fig. 2.3 The infra-red spectrum of compound **D**

Fig. 2.4 The  $^1\text{H}$  NMR spectrum of compound **D**

- (ii) Use Fig. 2.3 and Fig. 2.4 to deduce the structure of **D**. Explain your reasoning.

[4]

**IR:**

| Wavenumber of absorbance / $\text{cm}^{-1}$ | Interpretation         |
|---------------------------------------------|------------------------|
| Strong absorption at $1700\text{ cm}^{-1}$  | C=O stretch in ketone  |
| Weak absorption at $3000\text{ cm}^{-1}$    | Alkenes $\text{--C=H}$ |

**NMR:**

| $\delta$ /ppm | Multiplicity | No. of adjacent protons | No of H | Deduction                                                                                                                                                     |
|---------------|--------------|-------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.90          | Doublet      | 1                       | 3       | $\text{--CH}_3$ adjacent to C=C and split by the proton on the far end of C=C ( $\text{H}_A$ or $\text{H}_B$ split by $\text{H}_C$ )                          |
| 2.11          | Doublet      | 1                       | 3       | $\text{--CH}_3$ adjacent to C=C and split by the proton on the far end of C=C ( $\text{H}_A$ or $\text{H}_B$ split by $\text{H}_C$ )                          |
| 2.19          | Singlet      | 0                       | 3       | $\text{--CH}_3$ adjacent to C=O (no H on adjacent C)                                                                                                          |
| 6.0           | Multiplet    | 6                       | 1       | $\text{=CH}$ adjacent to $(\text{CH}_3)_2\text{C=}$ and split by the protons on the two $\text{CH}_3$ ( $\text{H}_C$ split by $\text{H}_A$ and $\text{H}_B$ ) |

Note:

Structure of **D**:

- (iii) By considering the structure of compound **C**, suggest a mechanism for the reaction of **C** with warm conc.  $\text{H}_3\text{PO}_4$  to produce **D**, and label the rate-determining step. [3]

**C** is a tertiary alcohol, so it is likely to undergo E1.

- (iv) The reaction of **C** with warm  $\text{H}_3\text{PO}_4$  could produce two possible constitutional isomers. Draw the structure of the other isomer, and suggest a reason why isomer **D** is formed, rather than the other isomer. [1]

**D** is more substituted and hence more stable.

(b) Another sequence of reactions starting with propanone is shown in Fig. 2.5.

Table 2.1 lists the peak in the  $^1\text{H}$  NMR spectrum of **F**.

**Table 2.1**

| $\delta/\text{ppm}$ | splitting pattern | number of H atoms |
|---------------------|-------------------|-------------------|
| 1.04                | singlet           | 12                |
| 2.33                | singlet           | 4                 |
| 2.70                | broad singlet     | 1                 |

The infra-red spectrum of **F** includes a strong peak at  $1700\text{ cm}^{-1}$  and a weak peak at  $3320\text{ cm}^{-1}$ .

Use the information given to suggest a structure for compound **F**.  
Explain your reasoning.

[4]

**IR:**

| Wavenumber of absorbance / $\text{cm}^{-1}$ | Interpretation                            |
|---------------------------------------------|-------------------------------------------|
| Strong peak at $1700\text{ cm}^{-1}$        | C=O stretch in ketone                     |
| Weak absorption at $3320\text{ cm}^{-1}$    | N-H in amines (since there is only one O) |

**NMR:**

| $\delta / \text{ppm}$ | Multiplicity  | No of H | Deduction                                                 |
|-----------------------|---------------|---------|-----------------------------------------------------------|
| 1.04                  | Singlet       | 12      | Four $-\text{CH}_3$ with no H on adjacent C               |
| 2.33                  | Singlet       | 4       | Two $-\text{CH}_2$ no H on adjacent C and adjacent to C=O |
| 2.70                  | Broad Singlet | 1       | $-\text{N}-\text{H}$ in amines                            |

Structure of **F**:

Note

**E** reacts with ammonia via nucleophilic addition. Ammonia can attack either at the carbonyl carbon atom or the electron-deficient disubstituted alkene C atom.

From the strong peak at  $1700\text{ cm}^{-1}$  in the IR spectrum, there is a C=O group in **F**, hence the nucleophile attacks at the disubstituted alkene C atom. The weak peak at  $3320\text{ cm}^{-1}$  corresponds to N-H stretch in the amine.

In the NMR spectrum, the broad singlet corresponds to 1 labile proton present in the amine N-H. From the relatively few number of signals and the even number of H atoms (except the broad singlet), compound **F** is likely to be symmetrical.
